

Kinect2VR

Integrating the Kinect with Immersive Virtual Technology

ABOUT

Kinect2VR is the innovative integration of the latest in motion-capture technology offered by Microsoft Kinect with the virtual environment rendering hardware of WorldViz. This system allows for the creation of virtual environments in which the user can interact with agent-avatars in real time using realistic physical movements.

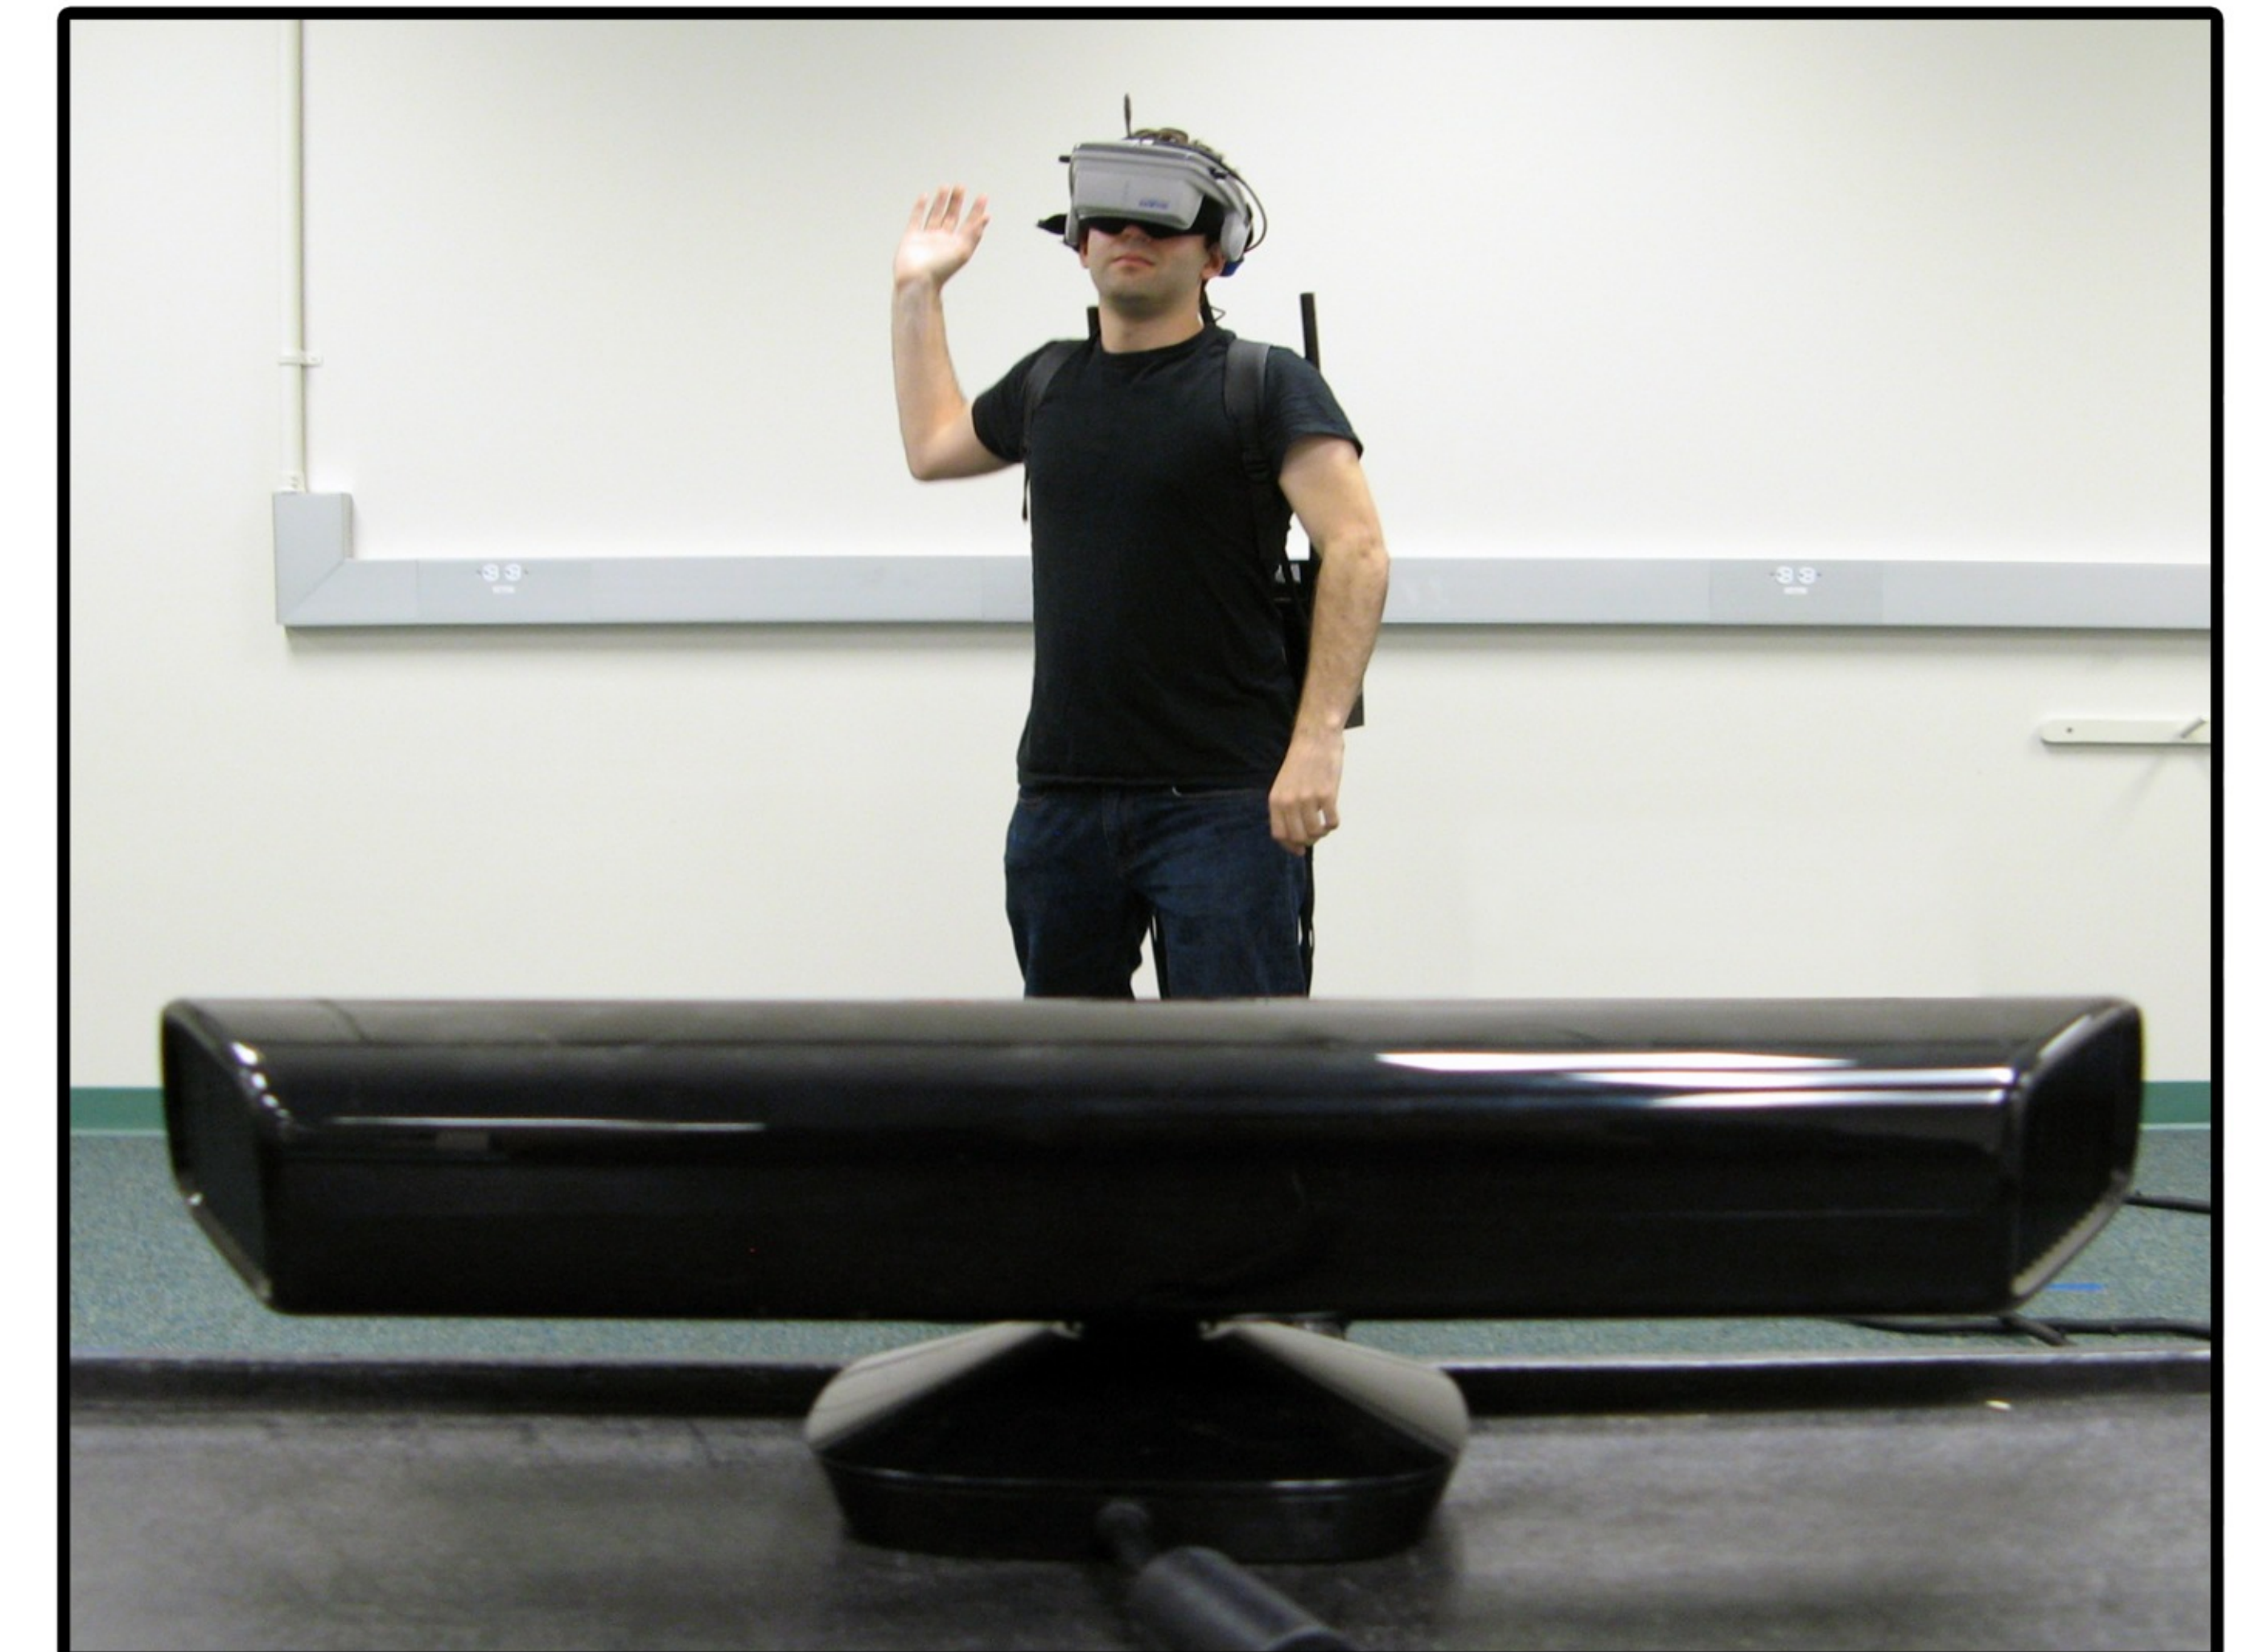

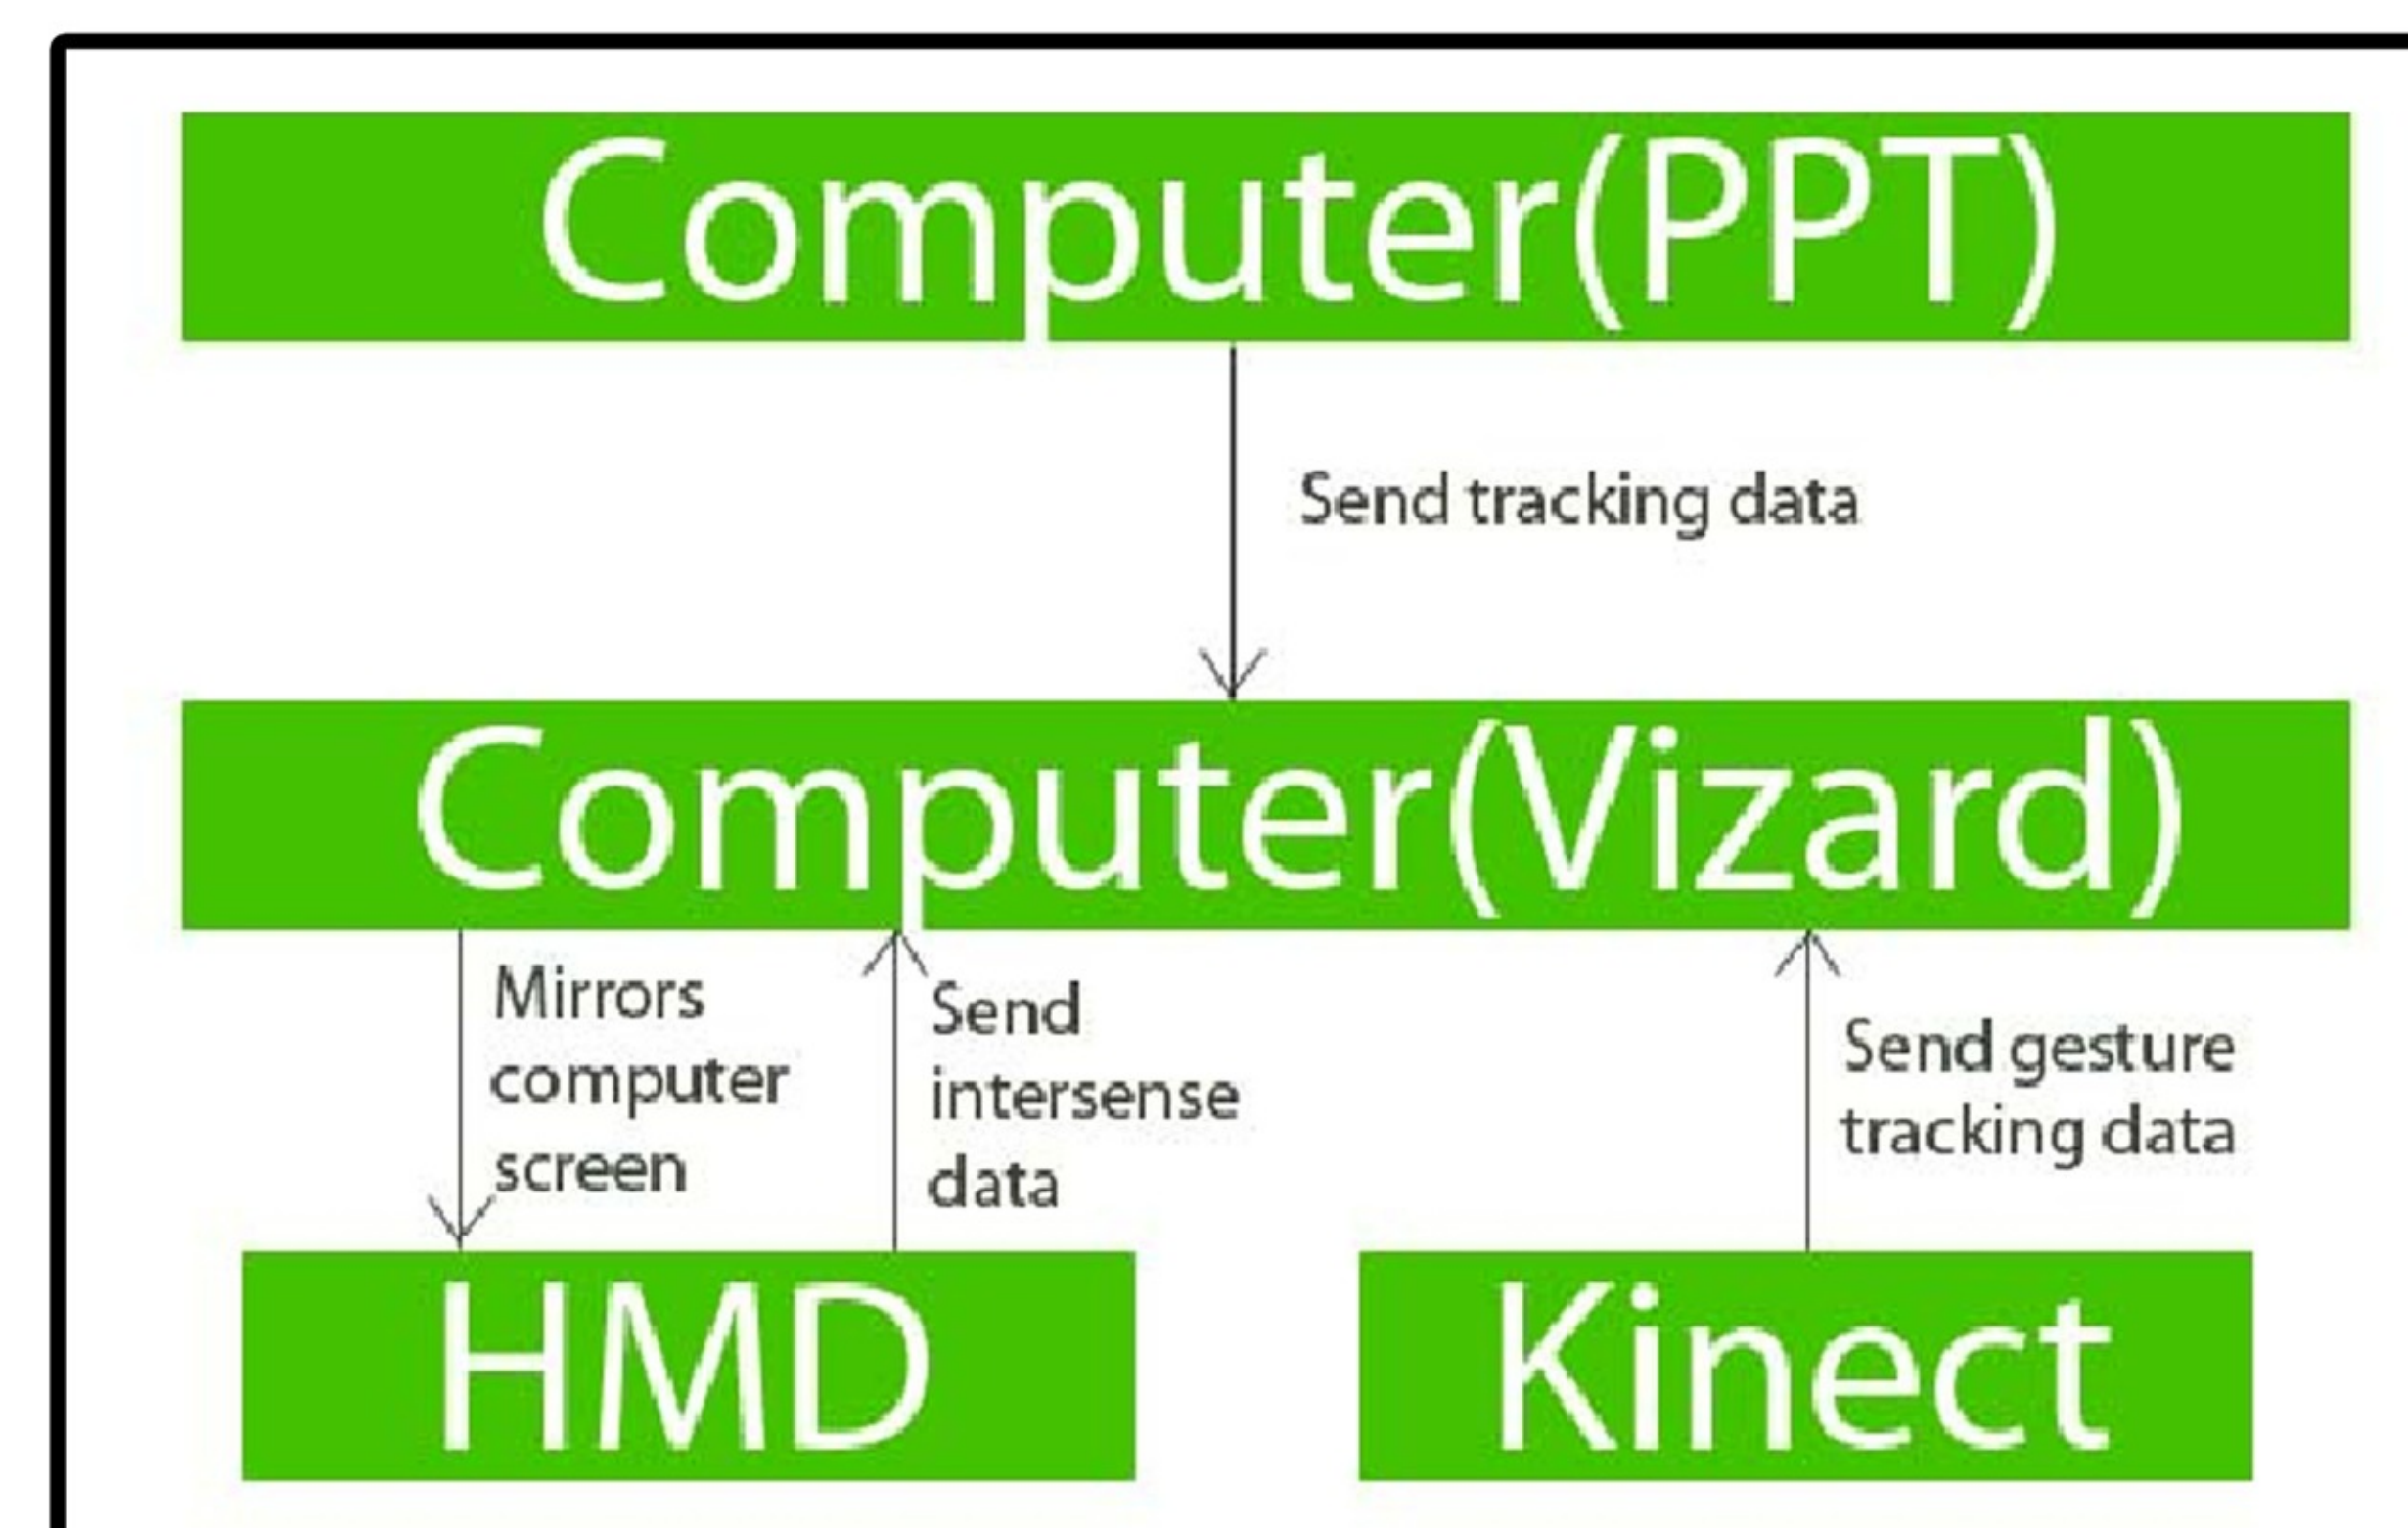

WHAT IS CYBERBALL?

Among the many well documented phenomenon in social psychology, ostracism is perhaps one of the most widely studied. Through a game called “cyberball”, researchers have been able to successfully manipulate feelings of inclusion or ostracism by having a participant play a ball tossing game with two computer controlled others. Perhaps the most impressive aspect of this well documented phenomenon is the robust effect produced with such a “low-tech” interface.

OUR CYBERBALL

Our Kinect version of the cyberball game addresses this obvious deficit. By immersing the participant in a three dimensional virtual world via a head mounted display (HMD), the experiences of inclusion and ostracism become more real and therefore produce more powerful effects. In the end, we were able to provide the researcher with a truly immersive experience with which they can test the effects of ostracism.
